In both [JavaScript](#) & [PHP](#) we have lots of Functions for making things work, would you add these when and how we needed for the task involved?

So my question is does anyone know of a [PHP Function Code Folder](#), that works on collecting the name of the Function from the filename and the data of that Function? Then the same [JavaScript](#) collect Functions from filenames also...

This would mean you could have folders for those Function files and through them add any virtual task with allot less hacking for most web-development globally.
